

Pictorial Anatomy Of The Fetal Pig

FETAL PIG PICTORIAL REVIEW

DIGESTIVE SYSTEM

Internal Organs *in situ*

When you finish making the initial cuts, you will be able to see many of the internal organs of the pig in their natural places.

The heart (1) lies in the middle of the thoracic cavity, surrounded by a membrane called the pericardium. If you have damaged the pericardium beyond recognition, look at someone else's pig. By the time you are done the dissection, all the pericardia will have been removed. The top of the heart will be covered with the thymus gland, which extends up into the throat. Much of the thymus has been removed from the pig pictured here.

On either side of the heart are the lungs (2). Note that the left lung is smaller. You will have cut the diaphragm (3), but it can still be seen, as can its attachment to the body wall.

The large liver (4) may vary from reddish brown to blue. The former is its natural colour, but blue latex often fills its numerous blood spaces.

Just behind the liver on the left side, the stomach (5) can be seen, and the spleen (6) wraps around the left side of the liver. The spleen is very delicate and may break when you try to separate it. It is not surprising that ruptured spleens are one of the most common types of internal injury.

The large umbilical vein (7) can be seen entering the liver. You had to cut this vein during the initial incisions. Its other end can be seen on the flap carrying the umbilical cord.

The intestines of a pig are arranged somewhat differently from those of a human. The pinkish coloured jejunum (8) is seen on the top right, the greener ileum (9) at the lower centre, and the coiled up colon (10) at the top left.

The urinary bladder (11) folds back with the umbilical cord, and is surrounded by the two large umbilical arteries (12). These arteries take blood from the fetus to the placenta, where it picks up nutrients and oxygen from the mother's blood, and loses waste products of the fetus's metabolism.
